## 2.1 Linear programming

(Natvig)

Do we need section introductions too?

### 2.1.1 Problem formulation. Standard and slack forms

The term *linear programming* (LP) refers to a type of optimisation problems in which one seeks to maximise or minimise the value of a linear function of a set of variables that are constrained by a set of linear equations and/or inequalities<sup>1</sup>.

Linear programming is a fairly general problem type, and many important problems (TODO) can be cast as LP problems — for instance, network flow problems and shortest path problems (see [?]).

(other than those problems that are initially formulated as an LP problem)

Throughout this report, we will consistently use  $n$  to refer to the number of variables and  $m$  to refer to the number of inequalities. The variables will typically be (TODO: spell “label(l)ed”)  $x_1$  through  $x_n$ .

The function to be optimised is called the *objective function*. In the real world situation that gives rise to an optimisation problem, the function may contain a constant term. However, since this term (TODO), we drop it from the objective function, which can then be written as  $f = c_1x_1 + c_2x_2 + \dots + c_nx_n = \sum_{j=1}^n c_jx_j$ , where  $c_j$  are the coefficient values.

(TODO)

Nonnegativity of variables, which is often the case in real world problems. Why are not less-than allowed?

The equations and inequalities that (together with the objective function) constitute an LP problem may be represented in different forms. We shall first consider the *standard form*, in which only less-than-or-equal-to inequalities with all variables on the left hand side are allowed. (TODO) A problem containing an

<sup>1</sup>Hence, LP is not (as the name would seem to suggest) a programming technique.

Should I label the coefficients  $a_{i1}, \dots, a_{in}$  instead to maintain consistency with the standard/slack forms?  
How to indent?

equalities of the form  $a_1x_1 + \dots + a_nx_n = b$  (Natvig) may be rewritten by splitting each equality into two inequalities:  $a_1x_1 + \dots + a_nx_n \leq b$  and  $-a_1x_1 - \dots - a_nx_n \leq -b$ . Also, the goal must be to maximise the objective function (if the original problem is to minimize  $f$ , we let our objective function be  $-f$ ). A linear program in standard form can be expressed as follows: (TODO)

Maximise

$$f = \sum_{j=1}^n c_j x_j$$

with respect to

$$\sum_{j=1}^n a_{ij} x_j \leq b_i, \text{ for } i = 1, \dots, m.$$

equation or equality?

The other common representation, which is employed by the simplex algorithm (to be presented shortly), is *slack form*, which only allows a set of equations (and a nonnegativity constraint for each variable). An inequality of the form  $a_1x_1 + \dots + a_nx_n \leq b$  is converted to an equation (TODO) by adding a *slack variable*  $w$ . Together with the condition that  $w \geq 0$ , the equation  $a_1x_1 + \dots + a_nx_n + w = b$  is equivalent to the original inequality (whose difference, or “slack”, between the left and right hand sides is represented by  $w$ ).
